

System Analysis

Existing System Analysis

In the existing system, ticket management is handled manually or semi-manually.

- Tickets are assigned manually by a support manager.
- No intelligent routing mechanism is implemented.
- Workload distribution among agents is uneven.
- Tracking ticket ownership and status is difficult.
- SLA monitoring is not automated.

Support requests are often handled through emails or spreadsheets, leading to delays and lack of transparency

Problems Identified

- Lack of automated ticket assignment
- Uneven workload distribution
- No centralized tracking mechanism
- Delays in response and resolution
- No proper SLA monitoring
- Limited visibility for support managers
- Communication gaps between support agents

The absence of automation and centralized monitoring reduces overall efficiency and increases ticket resolution time.

Proposed System Analysis

- Incidents will be created in the Incident table.
- Assignment Rules will automatically assign tickets based on category and priority.
- Flow Designer will manage automation workflows.
- SLA policies will monitor response and resolution time.
- Dashboards will provide real-time ticket tracking.
- Role-based access control will ensure security.

This system ensures faster routing, balanced workload distribution, and improved accountability

Feasibility Study

Technical Feasibility

The ServiceNow platform provides built-in features such as:

- Incident Management
- Assignment Rules
- Flow Designer
- SLA Management
- Reporting & Dashboards

No additional infrastructure is required.

Operational Feasibility

- Easy-to-use web interface
- Minimal training required
- Automated notifications improve communication

Economic Feasibility

- Implementation using ServiceNow Developer Instance (Free)
- No additional licensing cost for development
